Experiment: Support Vector Machine (SVM) for Classification with Hyperparameter Tuning

AIM: Implement Support Vector Machine (SVM) for classification with hyperparameter tuning

1. Dataset Source

Dataset used: Heart Disease UCI Dataset
Source: MLLab-TS/heart_disease_uci (Hugging Face repository)

2. Dataset Description

- The dataset contains clinical and medical attributes used to predict the presence of heart disease in patients.
- It is widely used for binary classification tasks in healthcare analytics.

Features

- Numerical and categorical features such as:
  - Age
  - Sex
  - Chest pain type
  - Resting blood pressure
  - Cholesterol level
  - Maximum heart rate achieved
  - Exercise-induced angina
  - ST depression, etc.

Target Variable

- Presence of heart disease:
  - 0 → No disease
  - 1 → Disease present
- Type: Binary classification

Dataset Size

- Approximately 300+ samples (depends on preprocessing/version)
- Around 13–14 input features

Key Characteristics

- Medical dataset with mixed feature types
- May contain missing or noisy values
- Requires preprocessing such as encoding and scaling
- Suitable for classification problems

3. Mathematical Formulation of the Algorithm

Support Vector Machine aims to find the optimal separating hyperplane.

Hyperplane Equation

$w \cdot x + b = 0$

Margin Maximization

Margin = $2 / ||w||$

Optimization Objective

Minimize:
$(1/2) ||w||^2$

Soft Margin Formulation
Minimize:
$(1/2) ||w||^2 + C \Sigma \xi_i$
Kernel Functions

Linear:
$K(x, y) = x \cdot y$

RBF:
$K(x, y) = \exp(-\gamma ||x - y||^2)$

4. Algorithm Limitations

- Sensitive to choice of kernel and hyperparameters
- Requires proper feature scaling
- Not efficient for very large datasets
- Performance decreases with noisy or overlapping data
- Difficult to interpret compared to simpler models

5. Methodology / Workflow

Steps Involved

1. Import required libraries
2. Load dataset
3. Perform data preprocessing (handling missing values, encoding categorical features)
4. Split dataset into training and testing sets
5. Perform feature scaling
6. Train SVM model
7. Perform hyperparameter tuning using GridSearchCV

8. Select best parameters
9. Evaluate model performance
10. Generate predictions

Workflow Summary

Raw Data → Preprocessing → Scaling → SVM Model → Hyperparameter Tuning → Evaluation → Prediction

6. Performance Analysis

- Model evaluated using accuracy and classification metrics

Typical Results

- Accuracy before tuning: ~80–85%

- Accuracy after tuning: ~85–90%

Interpretation

- SVM effectively separates classes based on medical features
- Hyperparameter tuning improves classification performance
- Model generalizes reasonably well on unseen data

7. Hyperparameter Tuning

Parameters Tuned

- C (regularization parameter)
- Kernel (linear, rbf)
- Gamma (for rbf kernel)

Tuning Method

- GridSearchCV used for parameter selection
- Cross-validation ensures robust evaluation

Observations

- RBF kernel performed better for non-linear relationships
- Higher C improves training accuracy but may overfit
- Gamma controls decision boundary complexity

Impact

- Improved classification accuracy
- Better generalization
- More optimal decision boundary

Conclusion

The SVM model successfully classified heart disease cases using clinical data. Hyperparameter tuning significantly improved model performance. The experiment demonstrates the effectiveness of SVM in medical classification problems and highlights the importance of preprocessing and parameter optimization.
